Abstract

Background: The rate of hypertension increases after menopause. Whether estrogen and progesterone deficiency associated with menopause play a role in determining a worst blood pressure (BP). Hypertension (HTN) is the leading risk factor for mortality and morbidity. Isometric handgrip (IHG) training is a simple intervention endorsed by the American Heart Association as a potential adjuvant BP-lowering treatment.

Aim of Study: This current study was designed to investigate the effect of isometric hand grip exercise on blood pressure on postmenopausal hypertension.

Subjects and Methods: Forty post menopausal women participated in this study they complained from hypertension (diagnosed clinically by gynecologist/physician), confirmed by sphygmomanometer instrument. They were selected randomly from outpatient clinic at Luxor general hospital, their age ranged from 50 to 65 years old, their body mass index were not exceed 35kg/m. and their blood pressure ranged from 140/90 to 180/110mm/Hg. They were divided randomly into two groups equal in numbers, group A consisted of 20 post menopausal women who received antihypertensive drugs and isometric hand grip exercise (4 sessions/week for 6 weeks). While group B consisted of 20 postmenopausal women who received anti hypertensive drugs only. Blood pressure was assessed by stethoscope and mercury sphygmomanometer for all patients in both groups before and after treatment.

Results: The result of this study revealed that, there was a statistically highly significant decrease in the mean value of SBP in both group (A&B) with percentage of improvement 12.0% and 8.4%, respectively. There was significant decrease in the mean value of DBP in both group (A&B) with percentage of improvement 16.27% and 9.47%, respectively.

Conclusion: It could be concluded that the isometric hand grip exercise is a simple, cost free and non pharmacological method in reducing blood pressure in post menopausal women and can be used as adjunct method in treatment of hypertension in postmenopausal women.

Key Words: Isometric hand grip exercise – Hypertension – Post menopause – Systolic blood pressure – Diastolic blood pressure.

Introduction

HYPERTENSION (HTN), defined as a systolic blood pressure (BP) ≥140mmHg and/or a diastolic BP ≥90mmHg, is a global epidemic. It is the leading cause of cardiovascular disease (CVD) and related mortality worldwide, and is responsible for ~10 million deaths each year, making it a substantial contributor to global chronic disease burden. HTN is the most commonly diagnosed condition in primary care [1].

Uncontrolled HTN is associated with several sequelae that are damaging to the cardiovascular system. Long-term and potentially fatal blood pressure-related complications include coronary artery disease, heart failure, stroke, and renal failure, in addition to cognitive decline and overall poor quality of life [2,3].

Hypertension is one of the leading risk factors for cardiovascular disease. Aging in both men and women is characterized by increases in blood pressure (BP), but the age-related increases are more rapid in women than in men, and the prevalence of hypertension in post-menopausal women is higher than in men. In the world, in general, 25% of adult women are hypertensive [4].

Hypertensive postmenopausal women had more co morbid conditions than did non hypertensive women, control of hypertension has been shown to reduce the risk of stroke or death in those with stage I (or mild) hypertension [5].

Aerobic exercise training has consistently been shown to reduce BP and improve autonomic func-
The Effect of Isometric Hand Grip on Blood Pressure

As detailed in recent meta-analyses (Owen, Wiles and Swaine, 2010) isometric handgrip (IHG) is intriguing exercise alternatives which require substantially less time (~30-75 total min/week) while documenting significant reductions in resting BP in normotensive and medicated hypertensive populations (similar to aerobic exercise training). Isometric handgrip (IHG) training improved local, endothelium-dependent vasodilatation in medicated hypertensive patients [7]. The studies, suggested that an absence of female gonadal steroids may represent a major risk factor for postmenopausal hypertension. These findings indicate that female gonadal steroids are a protective factor against increases in blood pressure. Menopause-induced estrogen loss changes the characteristics of blood vessels and responses to vasoactive substances. Hence, estrogen clearly constitutes an important factor in controlling blood pressure, and appears to exert the opposite effects from testosterone for the control of blood pressure [8].

Furthermore, epidemiological data indicate that regular exposure to isometric activity at the workplace lowers the incidence of hypertension.

These findings suggest that isometric exercise training may become an important part of a non-pharmacological intervention to prevent and combat hypertension) [9].

Isometric hand grip training may be especially beneficial for patients who:
- Have difficulties continuing or increasing drug-based treatment care.
- Are unable to attain BP control despite optimal treatment.
- Have pre-HTN or low-risk stage I mild-HTN
- Who wish to avoid medications or have less antihypertensive pill burden [10].

**Subject and Methods**

**Subjects:**
This study was carried out on a random sample of forty hypertensive post menopausal women and it was conducted for 6 weeks. The patients were chosen from Outpatient Department of Internal Medicine at Luxor general hospital in Luxor Governorate (From August 2018 to January 2019). Their ages were ranged from (50-65) years old, their body mass index (BMI) didn’t exceed 35 and their blood pressure from 140/90mmHg to 180/110mmHg. Duration of the study was 6 months.

All participants were given a full explanation of the treatment protocol and informed consent form had been signed by each women in both groups (A& B) before participated in this study.

**General characteristics of the women in both groups:**

The mean values (± SD) of age, weight, height and BMI in group (A) were 54.75±3.02 yrs., 80.35±6.43kg, 1.62±0.04m and 30.75±2.95kg/m², respectively while in group B they were 55.75 ± 3.64 yrs., 80.20±6.85kg, 1.64±0.05m and 29.85 ±3.24kg/m², respectively. Subjects with history of Hand burn, scar and contracture, with tendon cut in hand, subjects with cardiac disease and Right hemiplegic patient (left stroke) were excluded from the study.

**Instrumentation:**

**Stethoscope:**

**Mercury column sphygmomanometer:** To measure blood pressure in both groups (A&B) pre & post treatment.

**Hand grip dynamometer to determine maximum voluntary contraction (MVC).**

**Spring loaded hand grip device:**

**Easily adjust resistance level from (10 to 40kg):**
- Comfortable anti slip handles fit any hand size.
- High quality stainless steel tension springs provide long lasting [11].

**Measurements:**

1- **Measurement of arterial blood pressure:**

The procedure was carefully and clearly explained to each womenin both groups (A)&(B), arterial blood pressure was measured from right arm while the participant was in sitting position. Three trials for measurement of blood pressure was taken then the mean was calculated before and after the end treatment (6 weeks). Participants were required to abstain from exercise 24 hours before all measurements were taken by the same investigator.

2- **Measurement of subject maximum voluntary contraction (MVC):**

By using hand grip dynamometer, value was be determined as highest value obtain in three attempts. The purpose of using a hand dynamometer is to measure the maximum isometric strength of the hand and forearm muscles. The hand dynamometer could be adjusted for hand size and must be calibrated regularly for consistent results. The patients held the dynamometer in the right hand being tested, with the arm at right angles with the
elbow by the side of the body. Adjust the handle of the dynamometer as necessary, making sure that the base rests on the first metacarpal (heel of the palm), while the handle rests on the middle of the four fingers. The patients then squeeze the hand dynamometer with maximum isometric effort for at least 5 seconds. The patient was required to not move any other part of the body and was encouraged to use maximum effort.

c- Treatment procedures:

All women had full illustration as well as, explanation about the protocol of the study and sign a written approved consent form before the study.

Duration of the study: 15min. Frequency: 4 times per week, for 6 weeks. position of woman: Sitting position with back supported, and the working arm extended forward.

1- The anti hypertensive drug with the same dose for all patients was given for both groups (A) & (B) all through the study period (6 weeks).

2- Isometric hand grip exercise was performed by 20 patients (group A) by using spring loaded hand grip with a resistance level that approximated 30% to 40% of their MVCs for 4 sessions/week for 6 weeks and home training exercise was explained to the patients.

3- Before starting first treatment session, each patient was instructed briefly about the treatment procedure, which was explained carefully to her to gain confidence and cooperation.

4- Women were in sitting position during training with the working arm extended toward front.

5- Before each training session each subject’s maximum voluntary contraction (MVC) value was determined by hand grip dynamometer as the highest value obtained on three attempts.

6- Patients performed four bouts (3min) of isometric hand grip exercise with the dominant hand by using spring isometric hand grip device at 30% of maximum voluntary contraction (MVC).

7- Each bout was separated by 5min rest period.

8- 20 subjects (Group B) didn’t train and served as control group.

Data analysis:

Measured data were analyzed and their mean values and standard deviation were calculated. Test of normality, Kolmogorov-Smirnov test, was used to measure the distribution of data measured pre-treatment: the distribution of data measured pre-treatment:

- Accordingly, comparison between normally distributed variables in the two groups was performed using unpaired t-test. Analysis of covariance (ANCOVA) test was used to compare the post-treatment values of the two groups on controlling the effect of pre-treatment value. Bonferroni correction test was used to compare within group (pre-vs post-treatment) differences.

- Statistical Package for Social Sciences (SPSS) computer program (version 19 windows) was used for data analysis. p-value ≤0.05 was considered significant.

Results

1- Demographic data:

1- General characteristics of the women in both groups:

The mean values (±SD) of age, weight, height and BMI in group (A) study group were 54.75±3.02 yrs., 80.35±6.43kg, 1.62±0.04m and 30.75±2.95 kg/m², respectively while in group (B) control group they were 55.75±3.64yrs., 80.20±6.85kg, 1.64±0.05m and 29.85±3.24kg/m², respectively.

There was no statistical significant difference between the two groups as regards age (t=–0.945, p=0.351), weight (t=0.071; p=0.943), height (t=–1.624; p=0.113) and BMI (t=0.927; p=0.360) (Table 1, Figs. 1-4).

Fig. (1): Mean values of age in both groups.
The percent decrease in DBP level in both groups A and B were 16.27% and 9.47%, respectively (Table 2).

**Between groups comparison:**

At pre-treatment, in groups A and B, the mean values (±SD) of DBP were 95.25±5.25 and 95.00±5.13, respectively. There was no statistical significant difference between the two groups (F=0.023 & p=0.880) (Table 2).

ANOVA test was used to compare the post-treatment values of the two groups on controlling the effect of pre-treatment value. The results of DBP revealed that there was a statistical significant decrease in its level in group A (79.75±6.38) when compared with its corresponding level in group B (86.00±6.20) (F=16.755 & p=0.001) (Table 2, Fig. 5).

Diastolic blood pressure (DBP):

**Within group comparison (intra group comparison):**

In group A, there was a statistical significant decrease in the mean value of DBP measured at post-treatment (79.75±6.38) when compared with its corresponding value measured at pre-treatment (95.25±5.25) with p-value=0.001 (Table 2, Fig. 5).

Also in group B, there was a statistical significant decrease in the mean value of DBP measured at post-treatment (86.00±6.20) when compared with its corresponding value measured at pre-treatment (95.00±5.13) with p-value=0.001 (Table 2, Fig. 5).

Systolic blood pressure (SBP):

**Within group comparison (intra group comparison):**

In group A, there was a statistical significant decrease in the mean value of SBP measured at post-treatment (137.50±11.06) when compared with its corresponding value measured at pre-treatment (156.25±10.75) with p-value=0.001 (Table, Fig.).
Also in group B, there was a statistical significant decrease in the mean value of SBP measured at post-treatment (141.75 ± 13.01) when compared with its corresponding value measured at pre-treatment (154.75 ± 11.29) with \( p \)-value=0.001 (Table 3, Fig. 6).

The percent decrease in SBP level in both groups A and B were 12.0% and 8.4%, respectively (Table 3).

**Between groups comparison:**

At pre-treatment, in groups A and B, the mean values (± SD) of SBP were 156.25 ± 10.75 and 154.75 ± 11.29, respectively. There was no statistical significant difference between the two groups (F=0.185 & \( p \)=0.669) (Table 3).

ANCOVA test revealed that there was a statistical significant decrease in the mean value of SBP in group A (137.50 ± 11.06) when compared with its corresponding level in group B (141.75 ± 13.01) (F=11.364 & \( p \)=0.002) (Table 3, Fig. 6).

### Discussion

In our study, there was there was a statistically highly significant decrease in the mean value of SBP in both group (A&B) with percentage of improvement 12.0% and 8.4%, respectively. There was significant decrease in the mean value of DBP in both group (A&B) with percentage of improvement 16.27% and 9.47%, respectively.

The result of the study agreed with those of Owen et al., (2010) who found that a simple programme of isometric exercise, in bouts of 20min undertaken three times a week, with a weekly exercise time of 1h, can reduce systolic blood pressure by about 10mmHg and diastolic blood pressure by about 7mmHg, in <10 weeks. These are very substantial reductions, comparable with those achieved with a single pharmacological agent and substantially more than the 3mmHg or so reduction resulting from regular dynamic exercise or from resistance exercise. The greater reductions in resting blood pressure for isometric exercise compared with other modes of exercise suggest that there might be a more powerful effect on resting blood pressure from isometric exercise.

The result of the study agreed with those of Garg, Rinku et al., (2014) who found that after10 weeks of IHG training performing 3min bouts of IHG exercise separated by 5 minute rest period for 3times weekly for 10 weeks, there was a significant reduction in resting systolic and diastolic blood pressure. IHG might be simple, cost effective and non-pharmacological method in decreasing blood pressure.

The result of this study agreed with those of Devereux et al., (2015) who found that 4 weeks of Isometric Exercise Training induced changes in immediate post-exercise blood pressure and index of baroreflex sensitivity responses. Furthermore, these altered immediate responses were associated with training-induced reductions in resting blood pressure. This is the first suggestion that very short-term (immediate) cardiovascular responses following isometric exercise may be important in defining chronic reductions in resting SBP following a period of IET. The significant difference in immediate post-exercise SBP slope intercept suggests that chronic exposure to an isometric exercise stimulus may alter post-exercise SBP control. Adaptations in immediate post-exercise responses may be important in defining resting SBP adaptations to isometric exercise training, as evidenced by the correlation between individual adaptations.
The Effect of Isometric Hand Grip on Blood Pressure

in immediate post-exercise responses and training-induced reductions in resting SBP [15].

The result of these study agreed with those Farah et al., (2017) who found that isometric hand grip training has been considered a promising intervention to reduce cardiovascular risk in adults, given the positive effects on cardiovascular variables. meta-analytical study showed a reduction in systolic blood pressure of 5mmHg in hypertensive. Another advantage of the handgrip exercise is its easy implementation that allows it to be carried anywhere, including at home [16].

Conclusion:

It could be concluded that the isometric hand grip exercise is a simple, cost free and non pharmacological method in reducing blood pressure in post menopausal women and can be used as adjunct method in treatment of hypertension in postmenopausal women.

تأثير تمرين مقاومة اليد على ضغط الدم بعد أنقاطع الطمث

الخلاصة: إن معدل الزيادة في ارتفاع ضغط الدم بعد سن اليأس، سواء نقص الاستروجين والبروجسترون المصاحبة لأنقاطع الطمث، يلعب دوراً في تحديد ضغط الدم ومدى ارتفاعه. ارتفاع ضغط الدم هو عامل الخطير الرئيسي للوفيات المرضية. تتم قياس قبضة اليد المتساوي القياس وتسجل بسيط معتمد من جمعية القلب الأمريكية كمعالجة محتملة لخفض ضغط الدم.

الغرض: تم تصميم هذه الدراسة الحاجية للتحقق من تأثير ممارسة اليد متساوي القياس على ضغط الدم بعد أنقاطع الطمث.

الطريقة: أربعون شخصًا من النساء بعد أنقاطع الطمث لديهن شاركن في هذه الدراسة. يعانون من ارتفاع ضغط الدم (تم تشخيصهم من قبل طبيب أمراض النساء/الطبيب). وأُجريت على أربعة مقياس ضغط الدم، ثم أخذت عينات عشوائية من العينات الخارجية بمستشفي الأقصر العام. تراوح عمرهم من 50 إلى 70 سنة، ولم يتجاوز مؤشر كليه الدم المسمى كيouters 300/160 م. وترحبت ضغط الدم لديهم من 60/100 إلى 110/180 م. تقييم طبقي، تم تقسيمهم بشكل عشوائي إلى مجموعتين متساويتين في الأعداد، المجموعة A تتألف من 20 نسخة، بعد أنقاطع الطمث في الjours ظرف. مجموعتين قياسية (مزققتين خافضًا للضغط ومارس بترين القبضة اليدوية (4، جلسات في الأسبوع لمدة 6 أسابيع). في حين تتألف المجموعة B من 20 نسخة بعد سن اليأس لقياس أداء ارتفاع ضغط الدم فقط. تم تقييم ضغط الدم بواسطة السمعة الطبية والرتبة لجميع المرضى في كل المجموعتين قبل وبعد العلاج.

النتائج: أظهرت هذه الدراسة أن هناك انخفاض نسبيًا في خط الحد الأقصى لضغط الدم (أ، ب)، مع نسبة تحسن 16.2% و 8.7% على التوالي. وكان هناك انخفاض ملحوظ في مستوى القيمة. الضغط الإضافي في كلا المجموعتين (أ، ب) مع نسبة تحسن 37.6% و 17.6% على التوالي.

الخلاصة: يمكن الاستنتاج أن التمرين اليدوي المشاش هو طريقة بسيطة وحالية من الكثافة وغير دوائية في خفض ضغط الدم عند النساء بعد أنقاطع الطمث، ويمكن أن تكون مساعدة في علاج ارتفاع ضغط الدم في النساء بعد سن اليأس.
