Abstract

Background: Management of uterine polyps is primarily based on the hysteroscopy and biopsy.

Aim of Study: Is to compare the diagnostic performance of transvaginal color Doppler sonography (TVCD) and sonohysterography (SHG) in the diagnosis of endometrial polyps.

Material and Methods: Thirty-four women (mean age, 38.6 years; range, 28-55 years) with clinical or B-mode sonographic suspicion of endometrial polyps were included in this prospective study. Transvaginal color Doppler sonography first and then SHG were performed in all patients. On TVCD, a polyp was suspected when a vascular pedicle penetrating the endometrium from the myometrium was identified. On SHG, a polyp was suspected when a focal polypoid lesion was seen within the endometrial cavity. All patients underwent hysteroscopy and endometrial biopsy, the findings of which were used as the criterion standard. Sensitivity and specificity for TVCD and SHG were calculated and compared by the McNemar test.

Results: Hysteroscopy and endometrial biopsy findings were as follows: 33 (97.1%) cases had endometrial polyps, while 4 (11.8%) had endometrial hyperplasia, 6 (17.6%) had endometritis, 2 (5.9%) had fibroids, and 2 (5.9%) had adenomyosis. Accuracy and $p$-value for TVCD and SHG were 58.82% and 0.441 and 91.17% and 0.005, respectively.

Conclusion: Findings showed that there was a significant difference between color doppler results and sono-hysterography findings. Saline infusion Sonohysterography is significantly more accurate than transvaginal color Doppler ultrasonography in the detection of endometrial polyps.

Key Words: Color Doppler sonography – Endometrial polyp – Sonohysterography – Hysteroscopy.

Introduction

UTERINE polyps are a common cause of vaginal bleeding in pre- and postmenopausal women, mostly benign; however, it carries risk of pre–malignancy. Hysteroscopic biopsy is the gold standard in diagnosis [1].

Uterine polyps are abnormal growth, with morphologic subtypes; sessile or elongated pedunculated lesions of different size that project into endometrial cavity. They are the most frequently observed pathological finding in the uterus.

They may be asymptomatic or symptomatic, causing irregular menstrual bleeding, bleeding between menstrual periods, excessively heavy menstrual bleeding (menorrhagia) [2], and vaginal bleeding after menopause [3]. It has been a causative relation between uterine polyps and infertility [4] how polyps engage in subfertility and pregnancy loss is unclear, even it can miscarriage women undergoing IVF it may interfere with sperm transport, embryo implantation, or intrauterine inflammation [5].

The pathogenesis and history of endometrial polyps is unknown, however there are theories believed to be related to estrogen stimulation. The risk factors for endometrial polyp formation includes obesity, increased endogenous estrogen, high blood pressure and exogenous estrogen administration (Tamoxifen, a uterine estrogen agonist used to treat breast cancer) [6].

Abbreviations:

AUB : Abnormal uterine bleeding.
D&C : Dilatation and curettage.
IVF : Invitro Fertilization.
MRI : Magnetic resonance image.
NSAIDs : Non-steroidal anti-inflammatory drugs.
SHG : Sono-hysterography.
SISH : Saline infusion sono-hysterography.
TVCD : Trans-vaginal color Doppler.
TVUS : Trans-vaginal ultrasound.

Diagnosis of uterine polyps can be done through: Transvaginal Ultrasonography (TVUS) which consider the primary modality for assessment of endometrial abnormalities [7], Colour flow doppler which demonstrate the feeding vessel of endometrial polyp (Fig. 1), Sonohysterography (saline infusion hysterogram) which is more accurate than ultrasound alone (Figs. 2,3), MRI because of its good soft tissue contrast resolution in cases of vaginal or cervical stenosis, Hysteroscopy and histological diagnosis is the gold standard [3,6,8,9].

Management of endometrial polyps is done through hysteroscopic polypectomy which is considered the most optimal treatment of endometrial polyps [7], also through Dilatation and curettage (D&C) however there is a potential for polyps to be missed due to their mobility [6].

The purpose of our study is to evaluate the diagnostic performance and the accuracy of Colour Doppler and saline infusion sonohysterography in diagnosis of endometrial polyps and comparing them with hysteroscopy & biopsy.

**Material and Methods**

**Study population:** A prospective study was conducted in the Radiology Department in Ain Shams University Hospital. The study was performed in 8-month period from March 2021 till October 2021, including 34 consecutive women patients aged from 28 to 55 years, with gynecological symptoms of menorrhagia, metrorrhagia and infertility. All patients included in the study were subjected to both transvaginal color Doppler sonography, saline infusion sonohysterography in the radiodiagnosis department and then patients is scheduled for hysteroscopic biopsy in early cancer detection & Gyn Endoscopy unit, Maternity Hospital, Ain Shams University.

Exclusion criteria included any patient not diagnosed with uterine polyp on grey sale U/S, patients with genital tract infection, pregnant women, women in late menstrual phase, intrauterine device, women with cervical stenosis or patulous os and women with endometrial cancer.

**Transvaginal color Doppler Ultrasound:** An informed verbal consent was obtained after explaining the procedure to the patient.

Examination was performed with the patient in a lithotomy position. All scans will be performed using the US scanner (LOGIQ P5 MACHINE) in two perpendicular planes with high-frequency trans-vaginal transducers. Grey scale and colour Doppler will be performed to confirm diagnosis by visualization of pedicle vascularity.

**Saline infusion sonohysterography:** Non-steroidal anti-inflammatory drug (NSAIDs) as ibuprofen (400mg) is administrated half an hour before the examination, the patient lies in lithotomy position and vaginal speculum is introduced then vagina is painted with antiseptic solution, the upper cervical lip is grasped with a vulsellum.

A silicone Foley catheter of gauge 10-16 (according to size of cervical canal) is flushed with saline to get rid of air then introduced through the internal os then bulb is inflated with 3ml of normal saline (or Intra-uterine insemination IUI catheter used to avoid balloon painful sensation), then speculum and vulsellum is removed.

Trans-vaginal probe is introduced, and 50ml of warm sterile saline is infused slowly to distend the endometrium cavity under real time guidance, uterine images and findings are noted by specialized radiologist, at the end of the examination the bulb is emptied, and catheter removed, after evaluating the endometrial cavity for thickness, irregularities, or lesions (polyps).

**Statistical analysis:** Statistical analysis was conducted using SPSS 22nd edition, numeric variables as age was presented in mean ± SD. Categorical data were presented in frequency and percentages, paired comparison of diagnostic modalities was conducted using McNemar test. Sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy were calculated using 2X2 contingency tables. Any p-value <0.05 was considered significant.

**Results**

A total of 34 females were include in our final analysis, they had a mean age 38.6 ± SD 5.7 years old range from 28 to 55 years old. Among the included patients 52.9% complained of menorrhagia, while 50% complained of metrorrhagia and 50% complained of primary or secondary infertility. Colored doppler findings among the included patients showed positive single feeding vessel findings in 55.9% while 44.1 % had negative doppler findings.

Sonohystrography revealed positive results in diagnosis of endometrial polyps among 88.2% of the cases while 11.8% were negative from any abnormal finding.

Histopathology examination of the obtained specimens showed that 33 (97.1%) had endometrial...
polyps, while 4 (11.8%) had endometrial hyperplasia, 6 (17.6%) had endometritis, 2 (5.9%) had fibroids, 2 (5.9%) had adenomyosis.

Paired comparison between Histopathology findings of endometrial polyps and color doppler findings showed that there was a statistically significant difference between histopathology results and color doppler findings with \( p \)-value 0.441.

Color doppler had a sensitivity 57.6% in detection of endometrial polys, specificity 100.0%, PPV 100.0%, NPV 6.7% and overall diagnostic accuracy 58.82%.

Paired comparison between Histopathology findings of endometrial polyps and sonohysterography findings showed that there was concordance between histopathology results and sonohysterography findings with \( p \)-value 0.005.

Sonohysteroagrapy had a sensitivity 90.9% in detection of endometrial polyps, specificity 100%, PPV 100%, NPV 25% and overall diagnostic accuracy 91.17%.

The figure showed high concordance between histopathology findings and sonohysteroagrapy, as positive results was 88.2% in sono-hystrography versus 55.9% in the color doppler versus 97.1% in histopathology examinations.
Negative 97.10%

Discussion

Histological examination is still the gold standard for uterine cavity pathologies such as endometrial polyps. The evaluation of abnormal uterine bleeding is traditionally based on histological diagnosis, established either with dilatation and curettage or endometrial biopsy. However, these diagnostic procedures are invasive, and they may not detect all of the endometrial abnormalities if performed alone [2].

Transvaginal sonographic measurement of endometrial thickness has been shown to be useful method for detecting endometrial disease. However, increased endometrial thickness is not a specific finding and may be caused by several conditions, such as endometrial polyps, hyperplasia, and cancer.

Transvaginal color Doppler sonography allows assessment of endometrial vascularization. Recent reports have shown that endometrial polyps exhibit specific vascular patterns on color flow mapping [10].

This study was conducted on total of 34 females were include in our final analysis, they had a mean age 38.6 ± SD 5.7 years old range from 28 to 55 years old.

There were 18 patients (52.9%) presented with menorrhagia as one of the symptoms, 17 patients (50%) presented with metrorrhagia as one of the symptoms and 17 patients (50.0%) presented with infertility as one of the symptoms.

According to our study, menorrhagia should be considered the most common symptom among clinical presentation of endometrial polyp’s patients with incidence of 52.9% which comes against a study by Alcázar et al., [10] who stated that 47% of the patients were asymptomatic.

SHG is a relatively inexpensive procedure that can be easily performed with no need for special skill. It provides a reliable diagnosis in the detection of endometrial polyps over TVS. However, hysteroscopy and endoscopic biopsies remain the decisive diagnostic tests.

SHG was described to be a simple, safe, accurate and cost-effective technique for detecting endometrial abnormalities [8].

Sono-hystrography in our study revealed positive results for endometrial polyps in 88.2% of the cases with accuracy 91.17% which comes in line with a study by Alcázar et al., [10] which reported SHG accuracy 96% while a study by Kamel et al., [8] reported diagnostic accuracy for SHG 93.3%.

Our study in Sonohystrography had a sensitivity 90.9% in detection of endometrial polyps, specificity 100%, PPV 100%, NPV 25% in line with Romano et al., [13] in which their study reported a sensitivity, specificity, positive and negative predictive value of 95%, 100%, 100% and 94% respectively, for SHG in detecting endometrial abnormalities including polyps.

In study for Kaveh et al., [2] found that saline infusion sono-hysterography (SISH) has a sensitivity of 87.9% and a specificity of 92.2% in the detection of endometrial polyps, results were consistent with the previous systematic review conducted in Vroom et al., [11] which reported a sensitivity of 86.5% and specificity of 91.1% for SISH in diagnosis of endometrial polyps.

In our study trans-vaginal color Doppler (TVCD) revealed positive findings for single feeding vessel in 19 cases out of 34 with 55.9% with sensitivity 57.6% in detection of endometrial polyps, specificity 100.0%, PPV 100.0%, NPV 6.7% and overall diagnostic accuracy 58.82%.

A study by Talaat et al., [12] by concluded that the pedicle artery sign has 94% sensitivity 100% specificity.

Cogendez et al., [13] have studied the sensitivity, specificity, and positive and negative predictive values of the single vessel pattern in diagnosing endometrial polyps were 80, 100, 100, and 69.2%, respectively.
However, provided that the only way to rule out the risk of malignancy is through hysteroscopy and biopsy, SISH can be used as a method to stratify patients with abnormal uterine bleeding (AUB) to go for more diagnostic work up and treatment with hysteroscopy. Nevertheless, hysteroscopy is an exceptionally sensitive method, allowing the exclusion of intracavitary pathology as well as treatment in the same sitting with proper tissue biopsy from the abnormal area, which can be of help in proper treatment planning.

Hysteroscopy was superior to both trans-vaginal color Doppler and sono-hysterography regarding discriminating between polyps and other endometrial lesions. We calculated 97.1% positive results among the cases for hysteroscopy for diagnosis of endometrial polyps nearly like Kaveh et al., [2] study which calculated a 0.92 (95% CI: 0.89-0.94) sensitivity and a specificity of 0.85 (95% CI: 0.81-0.88) for hysteroscopy.

This study used histological diagnosis as the gold standard and assessed the accuracy of trans-vaginal color Doppler and saline infusion sono-hysterography in predicting endometrial polyps.

Histopathology examination of the obtained hysteroscopic specimens showed that 33 (97.1%) of cases had endometrial polyps, while 4 (11.8%) had endometrial hyperplasia, 6 (17.6%) had endometritis, 2 (5.9%) had fibroids and 2 (5.9%) had adenomyosis.

Our study showed that there was concordance between histopathology results and sono-hysterography findings with $p$-value 0.005.

A study performed by Cepni et al., [14] showed a sensitivity of 94% and a specificity of 58% for hysteroscopic diagnosis of endometrial polyps.

Our study showed high concordance between histopathology findings and sono-hysteroscopy, as positive results was 88.2% in sono-hysterography versus 55.9% in the color doppler versus 97.1% in histopathology examinations.

Conclusion:

As per our results, color doppler findings of endometrial polyps and sono-hysterography findings showed that there was a significant difference between color doppler results and sono–hysteroscopy findings while there was high concordance between histopathology results and sono–hysteroscopy findings.

Which prove the superiority of sono-hysteroscopy over color Doppler sonography in diagnosis of uterine polyps.

Sono-hysteroscopy results closely correspond to those obtained in a hysteroscopic examination combined with histopathological analysis.
