Corneal Epithelial Mapping Among Healthy Egyptian Eyes of LASIK Age Group Using Spectral Domain Anterior Segment Optical Coherence Tomography

MERVAT M. ABD EL BAKY, M.Sc.; AHMED H. ASSAF, M.D.; MOHAMED G. METWALLY, M.D. and TAMER A. BADRAN, M.D.
The Department of Ophthalmology, Faculty of Medicine, Ain Shams University

Abstract

Background: A good knowledge of the corneal epithelium distribution may help a lot in many aspects of clinical work such as screening of keratoconus before corneal surgery, fitting contact lens, and increasing the accuracy of corneal refractive surgeries. Such compensatory epithelial changes are seen in cases of asymmetric LASIK flaps, flap malposition and irregular stromal surface following multiple refractive procedures.

Aim of Study: To evaluate corneal epithelial thickness (CET) changes using Spectral domain-anterior segment optical coherence tomography (SD-AS-OCT) and to illustrate the distribution and variation of CET in healthy Egyptian eyes of LASIK age group (ranging from 18 to 50 years as long as the healthy condition of the cornea).

Patients and Methods: This prospective descriptive cross-sectional study was performed to assess epithelial thickness data on a sample of the Egyptian population. This comprised 200 eyes from 100 healthy Egyptian adults (50 males and 50 females), whose ages ranged from 18 to 50 years. Subjects were recruited from the outpatient clinic of ophthalmology of Ain Shams University Hospitals from January 2020 to December 2020.

Results: Our study demonstrated the epithelial layer of the cornea had a non uniform thickness profile, as suggested in previous studies. We found the thickest part was at inferior sector and the thinnest sector was superior. Our study showed the tear meniscus height was 300 µm on average. This may influence the result of the corneal epithelium distribution especially the differences between different locations.

Conclusion: Our study reports there was no statistically significant difference between males and females regarding epithelial thickness in different parts of the cornea.

Key Words: SD-AS-OCT – CET – PTK.

Introduction

CORNEAL refractive properties such as central corneal thickness (CCT), anterior curvature, posterior curvature, total corneal power are useful in all types of refractive surgeries. Moreover, understanding how these surgeries affect the corneal shape and structure is becoming increasingly important [1].

The corneal epithelium plays an important role in the optics of the eye. It maintains the corneal integrity and function and influences tear film stability. The contribution of the corneal epithelium to the refractive power of the cornea, and thus ocular refraction, cannot be ignored. Studies have shown that epithelial refractive power alone is an average of 1.03 D (range 0.55-1.85 D) over the central 2 mm diameter zone and 0.85 D (range 0.29-1.60 D) at the 3.6mm diameter zone [2].

The alterations of corneal epithelial thickness (CET) are found in many pathological conditions which have irregular corneal stromal surface to get a regular surface such as contact lens warpage dry eye and keratoconus [3].

Knowledge of the topographic CET profile and how it can change has been applied in clinical evaluation of various corneal disorders and in refractive surgery. Some corneal surgery and refractive surgery with excimer laser ablation were done directly on corneal epithelium such as transepithelial photorefractive keratectomy (trans PRK) and photo therapeutic keratectomy (PTK) [4,5].

Several imaging modalities, such as high frequency scanning ultrasound bio microscopy, confocal microscopy and optical coherence tomography (OCT) have facilitated measurement of CET [6].
Some of these techniques have some limitations as they are invasive devices and need to be anesthetic. This may increase the risk of corneal infection and decrease the accuracy because of the possible contact related corneal compression [7].

Since the latest years SD OCT has become a promising method to study the corneal epithelial thickness because its non invasiveness, good repeatability and accuracy at the same time [8,9].

Optical coherence tomography (OCT) is a non-contact optical signal acquisition and processing device that provides magnified, high resolution cross-sectional images of ocular tissues. Development of anterior segment OCT (AS-OCT) offers the benefits of fine resolution and noninvasive examination of the anterior segment anatomy to the depth of the iris plane. This imaging device has been utilized for investigating a variety of corneal and anterior segment diseases [10].

Technological advances toward three-dimensional visualization broaden the scope of AS-OCT in ophthalmologic evaluation. The AS-OCT is a valuable imaging tool whose use in research and clinical practice will continue to expand our knowledge and management of various ophthalmic conditions [11].

Aim of the work:

To evaluate corneal epithelial thickness (CET) changes using Spectral domain-anterior segment optical coherence tomography (SD-AS-OCT) and to illustrate the distribution and variation of CET in healthy Egyptian eyes of LASIK age group (ranging from 18 to 50 years as long as the healthy condition of the cornea).

Patients and Methods

This prospective descriptive cross sectional study comprised 200 healthy eyes from 100 subjects (50 males and 50 females), whose ages ranged from 18 to 50 years (mean ± standard deviation: 27.13±5.21 years).

Subjects were recruited from the outpatient clinic of ophthalmology of Ain Shams University Hospitals.

The study was conducted in accordance with the ethical standards stated by the Ethical Committee of Ain Shams University. Informed consent was obtained from each participant following the explanation of the academic nature of the study.

Inclusion criteria: Age: 18-50 years old (myope, hypermetrope, astigmatic), Sex: Males and Females and Able and willing to complete the required examinations.

Exclusion criteria: Pediatric subjects, Any corneal pathology, Major or minor ocular surgeries, Moderate or severe dry eye, Ocular trauma, Contact lens use and Blepharitis/meibomitis.

Inability to complete the required SD-OCT scans (e.g., unable to fixate due to poor vision).

The study was conducted in accordance with the ethical standards stated by the Ethical Committee of Ain Shams University. Informed consent was obtained from each participant following the explanation of the academic nature of the study.

All subjects were subjected to the following workup:

1- Corneal tomography by anterior segment OCT (epithelial mapping) Opti-vue.
2- Tear meniscus height measurement by ant segment OCT.
3- Refraction by using non-cycloplegic autorefractor (Huvitz HRK 7000, Huvitz Co., Ltd., South Korea).
4- Fundus examination by using non-contact fundus biomicroscopy through volk 90D lens.
5- As previous studies have reported no significant difference between eyes in the same individual. Each subject was scanned with each device by the same examiner on the same day.

Statistical analysis:

Data were collected, revised, coded and entered to the Statistical Package for Social Science (IBM SPSS) version 20. The qualitative data were presented as number and percentages while quantitative data were presented as mean, standard deviations and ranges.

Data were subjected to analysis by SPSS and Microsoft excel programs 2016. Repeated measure ANOVA with post hoc test was done and the statistical significance was set at \( p \)-value less than 0.05.

The comparison between two paired groups with quantitative data and parametric distribution was done by using Paired \( t \)-test.
The comparison between two independent groups with quantitative data and parametric distribution was done by using Independent \( t \)-test.

Spearman correlation coefficients were used to assess the correlation between two quantitative parameters in the same group.

The confidence interval was set to 95% and the margin of error accepted was set to 5%. So, the \( p \)-value was considered significant as the following: \( p>0.05 \): Non significant, \( p<0.05 \): Significant and \( p<0.01 \): Highly significant.

Results

This prospective descriptive cross-sectional study was performed to assess epithelial thickness data on a sample of the Egyptian population. This comprised 200 eyes from 100 healthy Egyptian adults (50 males and 50 females), whose ages ranged from 18 to 50 years.

The study was conducted on 100 persons (50 males and 50 females) (100 right eye and 100 left eye) whose age ranged from 18 to 50 years Mean ± SD 27.13±5.21 divided into 4 groups: (18-26) and accounts (46.0%), (27-34) and account (46.0%), (35-42) and account (5.0%), (43-50) and account (3.0%).

The previous table shows no statistically significant difference between males and females regarding epithelial thickness in different parts of the cornea.

Epithelial thickness was 0.56 \( \mu \text{m} \) thicker in male subjects than in female subjects.

Also, the previous table shows that there was no statistically significant correlation found between TMH of the studied subjects and epithelial thickness.

Discussion

The distribution of corneal epithelial thickness is quite different from that of corneal thickness.

Our study showed the tear meniscus height was 300 µm on average. This may influence the result of the corneal epithelium distribution especially the differences between different locations.

A good knowledge of the corneal epithelium distribution may help a lot in many aspects of clinical work such as screening of keratoconus before corneal surgery, fitting contact lens, and
increasing the accuracy of corneal refractive surgeries [12].

A prospective descriptive cross-sectional study included 200 eyes were divided into 4 groups.

Our aim to study the corneal epithelial thickness in healthy corneal conditions using anterior segment optical coherence tomography.

Our study demonstrated the epithelial layer of the cornea had a non-uniform thickness profile, as suggested in previous studies.

Our study reports no statistically significant difference between males and females regarding Epithelial thickness but the thickness of males was thicker by 0.56 µm than female subjects on the central part.

Some reports of the cornea being thicker in men than in women [13,14] and some suggestions that endocrine differences may affect ocular tissue growth. In spite of this potential hormonal influence on corneal thickness, the exact role is obscure.

In this study, males had a thicker corneal epithelium thickness than females in almost all sections; they had a 0.56 µm thicker epithelium in the center M-F=0.56 µm average, (p<0.140). Kanellopoulos et al., [14] and Wu et al., [7] agreed with our findings; however, their studies show slightly greater differences in the central epithelium with 1.52 µm and 1.34 µm respectively. Research has shown the influence of gonadal hormones on ocular development [15,16]; perhaps this can explain the difference.

Samy et al., [6] and Hashmani et al., [17] also found Males had a thicker epithelium than females in all locations there was no statistically significant difference between the two sexes by age or refractive errors as our study.

Our study we found the thickest part was at inferior nasal sector, and the thinnest part at the superior sector.

The thinner superior epithelium has been attributed to the effect of blinking and friction produced by the eyelid.

The corneal epithelium in normal eyes was slightly thicker inferiorly and nasally.

In all studies, inferior-superior difference was always larger than the nasal-temporal difference [13,18]. There are several theories for vertical asymmetry in epithelial thickness. First, as hypothesized by Reinstein et al., friction due to blinking abrades the epithelium of the cornea with a larger force applied on the superior meridian. Second, as suggested by Du et al., [16] the constant force applied by the upper eyelid on the superior meridian causes long-term thinning. The upper eyelid covers a greater part of the eye when compared to the lower eyelid and also applies a greater force on the cornea due to gravity. Lastly, as theorized by King-Smith et al., [19] the flow of the tear film with subsequent pooling in the inferior meridian may cause a falsely thick reading.

Reinstein et al., [20] reported a similar result in the use of very high-frequency (VHF) digital ultrasound some previous studies also reported that the inferior side is thicker than the superior, just like this study did.

The nasal epithelium being thicker than the temporal is a previously reported unexplained finding. The reason could be due to the fact of the nasal cornea is more protected than the temporal cornea.

In study by Buffault et al., [8] the Central 52.5±3.6, inf 53.5±3.4, sup 50.4±3.3, min 46.2±4.9, max 57.0±3.6.

In study by Catalan et al., [21] the Central 52±4.07, inf 53.14±4.50, sup 53.27±4.25, min 49.09±4.74, max 56.86±4.52.

In study by Wu et al., [7], the central part was 53.26±2.66 µm.

In this study by Samy et al., [6] the mean CET found to be 49.21±2.24 µm. The superior thickness was 48.61±2.25 µm, Inferior thickness was 49.60±2.16 µm. Minimum thickness was 48.0±2.15 µm, maximum thickness was 50.45±2.14 µm.

Agarwal [23] reported mean epithelial thickness of 58.5±2 µm on Fourier domain OCT. Tao et al., [24] reported thickness of 52.5±2.4 µm on Fourier domain OCT. Sin and Simpson [25] reported thickness of 52±3 µm on time domain OCT while Reinstein et al., [20] reported thickness of 53.4±4.6 µm on Artemis 1 (Arc Scan) very high-frequency digital ultrasound. Yang et al., [26] reported average CET (53.2±2.9 µm) measured by OCT system (Optovue, Inc., Fremont, CA) in the range of (48.0-59.9 µm). Rush et al., [13] reported a mean CET of 51.0 µm with a range of 43 to 61 µm. The average central
CET reported by Kim et al., [18] falls within the range of (48.0-59.9 gm).

Ethnic variability could be a considerable factor in CET. Our study includes only healthy Egyptian adults of all ages, the results demonstrated that gender was not correlated with CET. In a study including only healthy Korean adults of all ages the results demonstrated that gender was correlated with CET [18].

In conclusion, epithelial mapping seems to be an important tool in a refractive surgeon’s armamentarium for differentiating suspicious from normal corneas and identifying those with true progression of corneal ectasia. The authors believe that the addition of the epithelial map to the preoperative refractive surgery workup and in postoperative evaluation in case of suboptimal results will go a long way in making more accurate management decision, with improved outcomes.

Since the SD-OCT is a non-contact procedure that is easy to perform and is not uncomfortable for the patients, it has the potential to become part of the routine examination for the diagnosis of early keratoconus and for determining candidacy for refractive surgery.

The possible explanation for the inconsistencies in the results of different studies could be the uncontrolled factors affecting the CET measurement such as gender, race, ethnic variability, refraction, tear film thickness, the climatic state in the tested region and using equipment of different technology.

We hope to have future imaging technologies with higher resolution, with capability to cover the entire cornea and with the ability to exclude tear film thickness in the measurement. All these will help in evaluation CET more accurately and confirm its association with aging.

Conclusion:

Our study reports there was no statistically significant correlation found between the gender of the studied subjects and epithelial thickness of the cornea.

دراسة سمك التنسجي الطالائي للقرنية
باستخدام الجزء الأمامي من التصوير الطبيقي البصري
في الفئة العمرية لتصحيح الأصرار بالليزر من المصريين

يعد قياس سمك التنسج الطالائي وسماكة نسجية القرنية بشكل متصل يمكن أن يسهل اكتشاف أمراض القرنية في مراحل مبكرة. وبعد القياس الدقيق لقيم الجزء الأمامي من العين أمر ضروري لقياس ما قبل الجراحة، وتخطيط وتمثيل جراحات البناء والتجديد وتصحيح الأصرار وعملية التحام الجروح من بعدها عملية.

التنسج الطلائي للقرنية مهم في المحافظة على تحديد القرنية وانتظام السطح الأمامي من سطح القرنية، وهو مهم أيضاً في قوة القرنية ووظائفها وتماسك طبقة الدمع في العين. هناك عدة عوامل ممكن أن تؤثر في سمك التنسج الطلائي من القرنية ومنها جافية العين، استخدام العدسات الاصطناعية، القرنية المخروطية وعمليات تصحيح الأصرار.

تم اكتشاف أن العوامل الديموغرافية وال病ية مرتبطة بسمك القرنية ويمكن أن تؤثر هذه العوامل أيضاً على التنسج الطلائي للقرنية.

المعرفة بالبطيوغرافيا للقرنية الأمامية مهمة في معرفة معظم أمراض القرنية وكيفية علاجها عن طريق عمليات تصحيح الأصرار.

يعتبر جهاز التصور المصطي الأمامي واحد من أفضل الأدوات في فحص الجزء الأمامي من العين حيث يسمح بفحص سريع للجزء الأمامي من العين دون ملاءسة العين بدون استخدام تخدير الموضع، وذلك من خلال جناة العرض أمام الكاميرا وهذا يوفر الراحة للمريض مع عدم حدوث خدش القرنية.

الهدف من البحث: أن الهدف من هذا البحث سيكون قياس التغييرات المختلفة التي تحدث في النسيج الطلائي للقرنية العين في مجموعة من المصريين التي تتراوح أعمارهم مع عملية تصحيح الأصرار بالليزر باستخدام التصور المصطي الأمامي.

نتائج البحث: تضمنت هذه الدراسة 100 شاباً (50 من الذكور و 50 من الإناث) التي تراوح عمرها بين 18 إلى 50 سنة.

وقد وجدت الدراسة عدم وجود فرق مع دلالة إحصائية بين الذكور والإناث فيما يتعلق بسمك التنسج الطلائي في جميع أجزاء القرنية ولكن سمك التنسج عند الذكور كان أكبر قليلاً بقدر 0.5 مم من الإناث في الجزء المركزي.
